## Abstract

This work contains solutions to the problem set I of Probabilistic Method 2016 at Courant Institute of Mathematical Sciences.

### Question 1.

1. Find  $m = m(n)$  as large as you can so that the following holds: Let  $A_1, \dots, A_m \subseteq \{1, \dots, 4n\}$  with all  $|A_i| = n$ . Then there exists a two coloring of  $\{1, \dots, 4n\}$  such that none of the  $A_i$  are monochromatic. Use a random *equicoloring* of  $\{1, \dots, 4n\}$ . (That is, choose uniformly from the  $\binom{4n}{2n}$  two colorings for which there are precisely  $2n$  Red and precisely  $2n$  Blue vertices.) Express your answer as an asymptotic function of  $n$ .

### Solution.

**Question 2.**

2. (-) Suppose  $n \geq 2$  and let  $A_1, \dots, A_m \subseteq \Omega$  all have size  $n$ . Suppose  $m < 4^{n-1}$ . Show that there is a coloring of  $\Omega$  by 4 colors so that no  $A_i$  is monochromatic.

**Solution.** By union bound, we have

$$\begin{aligned} P\left(\bigvee_{i=1}^n \{A_i \text{ is monochromatic}\}\right) &\leq \sum_{i=1}^m P(\{A_i \text{ is monochromatic}\}) \\ &= m \cdot 4^{1-\binom{n}{2}}. \end{aligned}$$

As  $m < 4^{n-1}$  and  $n \geq 2$ , it follows that

$$\begin{aligned} m \cdot 4^{1-\binom{n}{2}} &< 4^{n-1} \cdot 4^{1-\binom{n}{2}} \\ &= 4^{\frac{n-n^2}{2}} < 1, \end{aligned}$$

which primarily grants us

$$P\left(\bigvee_{i=1}^n \{A_i \text{ is monochromatic}\}\right) < 1.$$

Therefore, the complement event of  $\bigvee_{i=1}^n$ , namely the event where no  $A_i$  is monochromatic, has positive probability. Hence, we have shown that there is a coloring of  $\Omega$  by 4 colors so that no  $A_i$  is monochromatic.  $\square$

**Question 3.**

3. (-) Suppose  $n \geq 4$  and let  $A_1, \dots, A_m \subseteq \Omega$  all have size  $n$ . Suppose  $m < \frac{4^{n-1}}{3^n}$ . Prove that there is a coloring of  $\Omega$  by 4 colors so that in every  $A_i$  all 4 colors are represented.

**Solution.**

**Question 4.**

4. The expected number of isolated trees [just take this as a fact] on  $k$  vertices in  $G(n, p)$  is given by  $f(n, k, p) := \binom{n}{k} k^{k-2} p^{k-1} (1-p)^B$  with  $B = k(n-k) + \binom{k}{2} - k + 1$ . Set  $p = \frac{1}{n}$ . Let  $c$  be a positive constant. Find (see Asymptopia, Chapter 5 or webnotes) for  $\binom{n}{k}$  the asymptotics of  $f(n, k, p)$  when  $k \sim cn^{2/3}$ . (\*) Express the limit as  $n \rightarrow \infty$  of the sum of  $f(n, k, p)$  for  $n^{2/3} \leq k < 2n^{2/3}$  as a definite integral and use a computer package to evaluate the integral numerically.

**Solution.**

**Question 5.**

5. (-) Consider Boolean expressions on atoms  $x_1, \dots, x_n$ . By a  $k$ -clause  $C$  we mean an expression of the form  $y_{i_1} \vee \dots \vee y_{i_k}$  where each  $y_{i_j}$  is either  $x_{i_j}$  or  $\bar{x}_{i_j}$ . Prove a theorem of the following form [you fill in the  $m = m(k)$ ] by the probabilistic method: For any  $m$   $k$ -clauses

$C_1, \dots, C_m$  there is a truth assignment such that  $C_1 \wedge \dots \wedge C_m$  is satisfied.

**Solution.**

**Question 6.**

6. Formula (13) on the n choose k notes (on the web) is applied with  $c = \frac{1}{2}$  to give the asymptotics of the middle binomial coefficient. Here we want to extend this to binomial coefficients near the middle.
- (a) (-) Give the Taylor Series for the Entropy function  $H(c)$  around  $c = \frac{1}{2}$  (set  $c = \frac{1}{2} + x$  for convenience) out to the quadratic term with error  $O(x^3)$ .
  - (b) Apply (13) to the asymptotics of  $\binom{n}{k}$  where  $k = \frac{n}{2} + u$  and  $u = o(n)$ , getting the answer in terms of the entropy function  $H(k/n)$ .
  - (c) Use the quadratic approximation of the Entropy function you derived above to get an asymptotic formula for  $\binom{n}{k}$  when  $k = \frac{n}{2} + u$  is sufficiently close to  $\frac{n}{2}$ . (You should get a rather (joke!) normal result.) To clarify: you are being asked to find a *scaling* which will be a simple function  $g(n)$  such that the sum of  $\binom{n}{k}$  over  $k \leq \frac{n}{2} + \lambda g(n)$  is a well known function of  $\lambda$ . You probably already know the answer via Central Limit Theorem but you are here asked to derive that answer through these asymptotics.

**Solution.**
